Ovitrap technique could be considered an efficient tool for monitoring of *Aedes* populations. This study aimed to monitor the dengue vector population and to provide baseline data of vector density in selected endemic areas. 1600 ovitraps were placed indoor and outdoor randomly in selected houses from January till July 2014 at eight selected localities. 96%–100% of ovitraps were recovered after seven days. In total, 9399 larvae were examined of which 2674 (28.2%) were *Ae. Aegypti* and 6752 (71.8%) *Ae. albopictus*. *Ae. albopictus* were dominant than *Ae. aegypti* in every locality. Highest collection of *Ae. albopictus* was recorded in Kampung Air (total larvae = 1357), followed by Kampung Bokara (total larvae = 1165) and Taman Fajar (total larvae = 846). Three main localities that recorded highest collection of *Ae. aegypti* were Kampung Bokara (total larvae = 504), Kampung Air (total larvae = 457) and Taman Fajar (total larvae = 341). *Ae. albopictus* was found more abundant compared to *Ae. aegypti*. The ovitrap index recorded in all localities (ranged 18.0% - 59.0%) was more than the transmission threshold (10%). Mix breeding of *Ae. aegypti* and *Ae. albopictus* were also detected for outdoor ovitraps. In conclusion, this study found that selected localities in Sandakan district have a high risk for transmission and outbreaks of dengue. Furthermore, this study also provided a baseline data of *Aedes* density for further planning of prevention and control activities.

Contribution/Originality: This study documents the ovitrap surveillance as an important tool for management and planning of dengue vector strategy focusing on endemic areas.

1. INTRODUCTION

Dengue is currently considered an important public health problem all over the world. Its occurrence has been notified and registered in more than 100 countries including most of tropical regions, China and Australia [1]. Malaysia had more than 38, 000 notified cases in each of the past six years [2]. In order to evolve an effective control mechanism, it is therefore very important to develop accurate methods that able to estimate adult population of *Aedes*. However, collection of sufficient numbers of *Aedes sp* indoors and outdoors is very difficult. In Malaysia, ovitrap and larval survey have been applied to monitor dengue vectors abundance in urban and suburban localities. Previous studies revealed that ovitrap was more effective than the larval survey for *Aedes* surveillance due to more numbers of *Aedes* were collected using ovitrap compared with larval survey [3-5]. Ovitrap surveys could be considered a sensitive and an efficient technique for detecting and monitoring *Aedes* populations at low densities and where the Breteau Index (BI) values are very low [6, 7]. Furthermore, the ovitraps are safe, economical and environment-friendly surveillance tools. Ovitrap is one of the cost-effective and important tools for

Aedes surveillance in dengue control [8]. Previous studies found that surveillance using ovitraps could be implemented for the prediction of outbreak, particularly in areas of low *Aedes* infestation, and has been suggested as a surveillance tool in dengue control [6, 7, 9]. Ovitrap surveillance is useful for management and planning of dengue vector strategy. This method is an important tool to provide spatial and temporal data in monitoring the impact of control measures [10]. Moreover, the application of ovitraps is advised for differentiating the infestation levels between the selected areas, focusing in high-risk areas [10]. Sandakan is one of the districts situated in Sabah, Malaysia and had recorded a significant number of dengue cases over the past three years (2011-2013). This study was conducted to monitor the dengue vector population and also to provide baseline data of vector density for further planning of control activities in selected endemic areas.

2. METHODOLOGY

2.1. Study Areas

Eight localities were selected for the implementation of ovitrap surveillance **Figure 1**. Those localities were selected based on the recorded cases and outbreaks of dengue fever from the year 2011 till 2013 in Sandakan district. The selected localities were Taman Fajar (TF), Taman Mawar (TM), Taman Airport (TA), Taman Kenari (TK), Taman Rajawali (TR), Taman Merpati Baru (TMB), Kampung Bokara (KB) and Kampung Air (KA) **Table 1**. A total of two hundred ovitraps were placed (indoor and outdoor) at randomly selected houses in each locality. Four ovitraps were allocated at each selected house (two were placed indoor, two were placed outdoor) [11].

2.2. Ovitrap Setting

The sampling of ovitrap as described by Lee [6] was applied in this surveillance based on the Malaysian Ministry of Health Guidelines [12]. Each ovitrap comprised of a 300 ml black plastic container (6.5 cm in diameter and 9.0 cm in height). Clean tap water was added until it reached the level of 5.5 cm and a hardboard paddle for oviposition (10 cm x 2.5 cm x 0.3cm) was placed with the rough surface facing upwards in every ovitraps. A total of 200 ovitraps were placed indoor (100 ovitraps) and outdoor (100 ovitraps) in randomly selected houses after obtaining consent from the house owner. Collection of ovitraps were done after seven days and transported to the Sandakan Health District Office laboratory. The contents of ovitrap including paddles were poured individually into covered and labelled plastic containers (15 cm x 7 cm x 8.5 cm).

In our study, indoor placement refers to the interior of the houses while outdoor placement refers to the outside of the houses but confined to house compound area only. As this study aimed to provide baseline data of *Aedes* abundance in all selected areas, therefore only one ovitrap surveillance was performed in each area. The surveillance of ovitrap was conducted in January till July 2014.

2.3. Identification of Larvae

The ovitraps were retrieved after 7 days and send to Sandakan Health District Office Vector laboratory. The identification was done by trained Public Health Assistants and the results were verified by entomologist. The contents of the retrieved ovitraps were poured into plastic container and labelled. Tap water (exposed for 24–48 hours before used) was added into the container. The larvae were counted and 3rd and 4th instar-larvae were identified based on the species key by Mahadevan, et al. [13]. The larvae were counted and identified under a

compound microscope (Nikon Eclipse E200, Japan) based on taxonomy keys. For each positive ovitrap, the larval numbers were recorded.

2.4. Data Analysis

The abundance of *Aedes* sp. larvae in selected endemic areas were analyzed as follows:

- i. Ovitrap index (Ovitrap Index), the percentage of positive ovitrap against the total number of ovitraps recovered for each site.

$$\text{Ovitrap Index (OI)} = \frac{\text{Number of positive ovitrap}}{\text{Number of ovitrap collected}} \times 100$$

- ii. The number of *Aedes* sp. larvae per recovered ovitrap.
- iii. Mean number of larvae (per species) per total number of recovered ovitrap for both or either indoor or outdoor:

$$\text{Mean number of larvae/ovitrap} = \frac{\text{Total number of larvae}}{\text{Total number of ovitrap collected}} \times 100$$

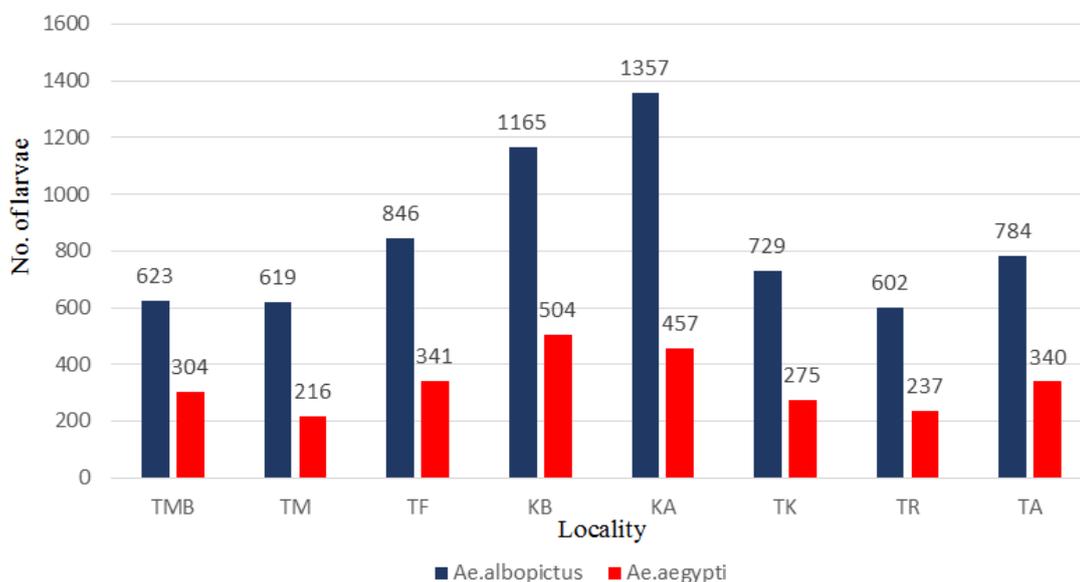

Figure-2. Total number of *Aedes* larvae collected using ovitraps in Sandakan, Sabah.

Table-2. Ovitrap index (OI) and mean number of *Ae. aegypti* and *Ae. albopictus* collected indoor and outdoor using ovitraps

Study area	Ovitrap placement	Ovitrap Index (%)	Mean larvae per recovered ovitrap	
			<i>Ae.aegypti</i>	<i>Ae.albopictus</i>
TMB	Indoor	20.0	6.25 ± 1.643	-
	Outdoor	30.6	-	9.86 ± 1.904
TM	Indoor	18.0	7.72 ± 2.109	-
	Outdoor	32.0	11.50 ± 3.536	11.52 ± 3.572
TF	Indoor	28.0	9.71 ± 1.823	-
	Outdoor	40.0	5.50 ± 0.707	9.97 ± 3.279

	Outdoor	30.0	5.33 ± 1.528	9.70 ± 1.462
TA	Indoor	33.3	8.25 ± 2.272	-
	Outdoor	35.1	5.50 ± 0.707	9.25 ± 2.170

3. RESULTS

A total of 1600 ovitraps were placed indoor and outdoor randomly in selected houses from January till July 2014. During the surveys, upon the placement of ovitraps, 96%–100% were recovered after seven days. In total, 9399 larvae were examined of which 2674 (28.2%) were *Ae. Aegypti* and 6752 (71.8%) *Ae. albopictus* Figure 2. *Ae. albopictus* were collected higher than *Ae. aegypti* in every study locality. Highest collection of *Ae. albopictus* was recorded in Kampung Air (total larvae = 1357), followed by Kampung Bokara (total larvae = 1165) and Taman Fajar (total larvae = 846). Three main localities that recorded highest collection of *Ae. aegypti* were Kampung Bokara (total larvae = 504), Kampung Air (total larvae = 457) and Taman Fajar (total larvae = 341). Overall, based on the total number of *Aedes* species collected during this study, *Ae. albopictus* was found more abundant compared to *Ae. aegypti*.

Table 2 summarized the ovitrap index (OI) and the mean number of *Ae aegypti* and *Ae albopictus* collected indoor and outdoor according to the study localities. The result showed that indoor and outdoor ovitraps were found positive with *Aedes* species at all study localities. The OI recorded in all localities was more than the transmission threshold (10%). This result indicated that the localities were considered at high risk of dengue transmission [9]. In this study, OI for indoor and outdoor were found to be in the range of 18%–48% and 30%–59% respectively. Highest OI for both indoor and outdoor were observed at Kampung Air with recorded mean larvae per recovered ovitrap of 12.00 ± 3.804 and 9.87 ± 1.884 followed by Kampung Bokara with recorded mean larvae per recovered ovitrap 9.74 ± 3.015 and 11.53 ± 3.421 . Mix breeding of *Ae. aegypti* and *Ae. albopictus* were identified for outdoor ovitraps at few localities such as Taman Mawar, Taman Fajar, Kampung Bokara, Kampung Air, Taman Kenari, Taman Rajawali and Taman Airport. However, no mix breeding of *Ae. aegypti* and *Ae. albopictus* were detected for indoor ovitraps.

4. DISCUSSION

This study utilized ovitrapping technique as *Aedes* surveillance tool and showed that it remains as economical and reliable tool to detect the abundance of *Ae. aegypti* and *Ae. albopictus*. Similar findings were reported by Braga, et al. [4]; Rozilawati, et al. [5]; Lee [6]; De Melo, et al. [14]; Noor Afizah, et al. [15] where the authors found that ovitrapping was a useful, more sensitive and effective to monitor *Aedes* infestation than standard larval survey activities.

Based on the result in Figure 2, it was found that *Ae. albopictus* population is highly abundant and dominated the selected localities in Sandakan district, Sabah especially as an outdoor breeder. This finding is supported by previous studies [5, 15, 16] which reported *Ae. albopictus* was more abundant and dominant outdoor than indoor. The total number of *Aedes* larvae collected from this study indicated that *Ae albopictus* and *Ae aegypti* as an outdoor and indoor breeder respectively. Although few studies in Malaysia [6, 17] reported that these two species can be found for both indoors and outdoors, *Ae aegypti* was predominantly identified to be dominant indoors and *Ae. albopictus* to be dominant outdoors as shown by this study. Kampung Air and Kampung Bokara which were located in coastal area of Sandakan district had recorded the highest number of indoor and outdoor *Aedes* larvae compared to other localities. This may due to the occurrence of outdoor breeding containers mainly plastic containers caused by improper waste disposal and management at these localities. The absence proper water supply system and refuse disposal has given rise of a large number of water storage containers both indoors and outdoors [18]. This led to high abundance of *Aedes* sp in the area that contributed to high oviposition in the ovitraps. Study by Mahmud, et al. [19] mentioned that one of the main *Aedes aegypti* indoor breeding container was water drum used as water storage container. As reported by Chang and Jute [18] the abundance of *Ae. albopictus* was higher in coastal and rural areas due to lack of basic infrastructures and constant water storage activities.

The results Table 1 revealed that more positive ovitraps were found outdoors rather than indoors in all localities which were correspond with previous study by Dibo, et al. [20]. In this study, the ovitrap index (OI) had indicated that all the localities were stratified as at high risk of dengue transmission (OI>10%) [9]. Therefore,

preventive and integrated control measures should be planned by vector control program in Sandakan district to eradicate *Aedes* breeding places as well as to enhance awareness on *Aedes* prevention among residents. To monitor the density of *Aedes* population and the risk of dengue transmission in these localities, we suggest that the surveillance of the mosquitoes to be continuously performed using standard ovitraps techniques [7, 21]. The variation of OI recorded in each locality may due to time variation, temperature and rainfall factors in Sandakan from January to July 2014. Data obtained from local authorities showed that there were increasing trend of temperature and rainfall data recorded in Sandakan starting from May to July 2014. Further investigation could be done to explore the relationship between meteorological factors with OI in these areas.

The results in Table 2 also demonstrated the existence of mix breeding for outdoor ovitraps at most of the study localities. Mix breeding of *Ae. aegypti* and *Ae. albopictus* were found in outdoor ovitraps at most of the localities and consistent with other studies in Indonesia and Malaysia [5, 22, 23]. Epidemiologically, mixed breeding is significant, as it is a demonstration of interspecific competitive displacement.

5. CONCLUSION

Our study manifested that the *Aedes* population can be observed and monitored effectively by applying ovitraps in selected localities continuously. Furthermore, this study provided a baseline data of *Aedes* density thus, assist for further planning of control activities in selected endemic areas. In conclusion, this study found that these selected localities in Sandakan district have a high risk for transmission and outbreaks of dengue. Findings from this study offered important entomological data for the development of effective integrated vector control program to combat *Aedes* in this area.
